Oversview: Vehicle dynamics control systems are roughly divided into three categories: brake, steering and suspension. The more sophisticated and specialized each category gets, the fewer manufacturers are capable of developing these systems comprehensively. Automotive Systems Group-centered Hitachi, Ltd., utilizes vehicle dynamics control actuation technologies, and is working to develop x-by-wire technologies, to improve the fundamental vehicle functions of driving, cornering and braking.

Introduction

Electric brake control technologies are being steadily developed and applied in stability control systems and brake-by-wire based on the ABS (anti-lock braking systems), and Hitachi, Ltd. has been working to develop electromechanical brake systems, in terms of future brake-by-wire, to the practical application phase.

Electronically controlled steering was initially limited to speed sensitive power steering systems. Now, SBW (steer-by-wire) will be central to future technologies.

Regarding suspension systems, semi-active suspension systems and active suspension systems have already been used in practical applications at the early stage to improve driving stability and ride quality. For the future, we focus on developing vehicle roll control systems and electromagnetic suspension systems to improve vehicle dynamics and driving safety.

Fig. 1—Image of a Concept Vehicle with ITS (intelligent transport system) Integrated Control. Shown is a concept vehicle equipped with x-by-wire developed by Hitachi, Ltd. The aim of this vehicle is to improve vehicle dynamics and layout.
**BRAKE SYSTEMS**

Since the ABS entered the practical application phase in 1978, electric brake control functions have been expanding. Recently, many functions have been used in popular vehicles, and Hitachi, Ltd. has already started mass-producing ABS and stability control systems. We are working to develop high-performance and high-functioning systems for the future, and we expect these systems will lead to x-by-wire (see Fig. 1).

**Stability Control Systems**

Stability control systems have appeared as the next-generation ABS. These are designed to control vehicle dynamics by regulating the brake force on each wheel and are the basis of x-by-wire, in terms of future chassis technologies. Hitachi, Ltd. has been mass-producing vehicle dynamics control units since 2001. It has developed master cylinder pressure sensor less systems, which estimate fluid pressure by controlling vehicle dynamics through vehicle deceleration and wheel speed. This reduces the size and cost of the stability control systems (see Fig. 2).

**Electromechanical Brake Systems**

Recently, vacuums generated in the engine have been lacking or have been insufficient for improved fuel efficiency, typically in HEVs (hybrid electric vehicles). For this reason conventional brake systems using engine vacuums are having difficulty in meeting the brake regulations. To overcome this problem electrohydraulic brake-by-wire has already been launched on the market.

The Hitachi Group (Hitachi, Ltd. and Hitachi Cable, Ltd.) is collaborating to develop its own electromechanical brake system as the brake system of the future. This will have the same brake functions as the electrohydraulic brake-by-wire, which are conventional brake functions and all the brake control functions, including ABS stability control, brake assist, and autonomous intelligent cruise control. It will also be possible to have additional functions such as electric parking braking.

There are many other advantages to the new system: less space is required in the engine and the driver’s compartment; it is more environmentally-friendly because no brake fluid is needed; it has a potentially better pedal feel; it can be operated by means of a joystick. In Hitachi Group, all the necessary technologies for the electromechanical brake system, namely conventional disc brake technologies, electric and electronic technologies, communication technologies, control technologies, and wire-harness technologies are available (see Fig. 3).

**STEERING SYSTEMS**

There are two types of power steering systems: electric power steering systems and hydraulic power steering systems. Currently hydraulic power steering...
systems are widely used, but electric power steering systems are rapidly coming into use, primarily in small passenger vehicles. Below, we detail the hydraulic power steering systems and electric power steering systems.

**Speed Sensitive Power Steering Systems**

Hydraulic power steering systems are capable of electronically adjusting the steering force according to vehicle speed, and are used primarily in luxury vehicles. Hitachi, Ltd.’s SSPS (speed sensitive power steering system) is capable of adjusting steering force by controlling the pressure control valves according to vehicle speed. This requires a relatively simple valve structure and makes possible highly responsive steering because it converts the fluid flow supplied by a pump to a pressure that efficiently operates a cylinder.

**Electric Power Steering Systems**

The pinion assist type electric power steering systems Hitachi, Ltd. is currently mass-producing consist of:

1. A torque sensor that detects steering force,
2. An electronic control unit that calculates signals from the torque sensor and supplies the necessary energy to the motor,
3. A motor that conveys an assist force to a pinion shaft through a reduction gear mechanism, and
4. A rack and pinion type steering gear.

The electronic control unit controls speed sensitive power steering systems by processing signals indicating the vehicle speed and the rotation of the engine. In addition, the torque limiter is positioned between the plastic gear in the reduction gear mechanism and the pinion shaft, and this protects the plastic gear from road surface pressure (see Fig. 4).

**Steer-by-wire**

SBW is a steering system for even greater safety and comfort than the existing systems described above. It allows the tires to move freely and it controls the speed in accordance with the steering because the steering system and the actuator that operates the tires are separate. The aim of this system is to improve safety and comfort in vehicle dynamics by reducing the number of steering corrections and by simplifying the steering system communication structure. SBW offers the additional advantage of flexibility in the interior design around the driver’s seat.

Hitachi, Ltd. is investigating optimal structures for the above-mentioned actuator that is the core of these systems and is also conducting R&D (research and development) for even greater safety and comfort through joint control activities with brake systems to evolve SBW into x-by-wire.

**SUSPENSION**

**Suspension Systems**

Suspension systems are the key component in driving pleasure and ride quality, and driving stability and ride comfort are the criteria for assessing these demands. Generally, the two do not exist together; sports vehicles for driving pleasure and luxury vehicles for ride quality each install the suspension system that fits its purpose better. Since electronically controlled adjustable shock absorber systems were released on
suspension systems to perform far better than semi-active suspension systems designed only to control the damping force.

Electromagnetic Suspension Systems

Hitachi, Ltd. is currently working to develop electromagnetic suspension systems using electromagnetics that became available as motor and inverter control technologies developed. Electromagnetic suspension systems are highly responsive and are expected to offer control at higher frequencies that are beyond the control of existing suspension systems. The systems currently in development use a linear motor without a reduction gear mechanism. This makes it easy to absorb the impact from road surfaces, and this improves ride quality.

CONCLUSIONS

Our top priority is to make vehicles with vehicle dynamics electric control systems on regular roads by providing them efficiently and at competitive prices. However, it is also essential to establish the new control logic necessary for these actuations. Hitachi, Ltd. is a leader in the development of future chassis technologies for x-by-wire. Both hardware and ideas will be the necessary basis for manufacturing x-by-wire vehicles.

On the one hand it is presumptuous of suppliers to boast “Provided we have vehicle parts, we can always complete a vehicle.” On the other hand, it is remiss of them to say, “We do not know a lot about vehicles although we deal with parts for the whole vehicle.” We at Hitachi are committed to offering what vehicles and vehicle dynamics are supposed to be from the standpoint of vehicle manufacturers.

ABOUT THE AUTHORS

Nobuyuki Ueki  
Joined Hitachi, Ltd. in 1999, and now works at the Chassis Department, the Marketing Division, the Automotive Systems. He is currently engaged in the planning of chassis products. Mr. Ueki is a member of Society of Automotive Engineers of Japan (JSAE), and can be reached by e-mail at nobuyuki.ueki.ge@hitachi.com.

Jun Kubo  
Joined Hitachi Unisia Automotive, Ltd. in 2002, and now works at the Chassis System Development Department, the Chassis System Division, the Automotive Systems, Hitachi, Ltd. He is currently engaged in the development of electric brake control systems. Mr. Kubo is a member of JSAE, and can be reached by e-mail at jun.kubo.ks@hitachi.com.

Toshio Takayama  
Joined TOKICO LTD. in 1979, and now works at the Advanced Technical Center, the Automotive Systems, Hitachi, Ltd. He is currently engaged in the development of electromechanical brake calipers. Mr. Takayama is a member of JSAE, and can be reached by e-mail at toshio.takayama.uj@hitachi.com.

Issei Kanari  
Joined Hitachi Unisia Automotive, Ltd. in 1976, and now works at the Steering Unit Design Department, the Chassis System Division, the Automotive Systems, Hitachi, Ltd. He is currently engaged in the development of a steering unit. Mr. Kanari is a member of JSAE, and can be reached by e-mail at issei.kanari.fn@hitachi.com.

Masaaki Uchiyama  
Joined TOKICO LTD. in 1987, and now works at the Technical Center, the 3rd Business Management Division, the Automotive Systems, Hitachi, Ltd. He is currently engaged in the development of electronic suspension control systems. Mr. Uchiyama is a member of JSAE and The Japan Society of Mechanical Engineers (JSME), and can be reached by e-mail at masaaki.uchiyama.cj@hitachi.com.
